Growth comparison knowledge

White standard edition

Record growth (links Science).

Measure before explaining

Use the existing marked shoots and the same selection and measuring method in both trays. Record height, opened whole-leaf count and condition. For a new height method, measure vertically from the medium surface to the main-stem growing tip without pulling or stretching. The adult models one whole expanded pea leaf at its stem attachment. Do not count leaflets, tendrils or stipules.

Check the comparison history

Before calling this a comparison kept differently since Week 2, the adult checks actual tray codes, starting measurements, the intended changed factor and care records. A fair comparison aims to change one factor while keeping the others alike. If the history or controls are unconfirmed, describe the current trays and state that the cause is uncertain.

Use careful conclusions

Height, leaf count and condition give different information. Taller alone does not mean healthier. Light, water and suitable warmth can affect growth, but one tray per condition and natural variation limit the conclusion. Keep both trays in suitable care. Never invent past conditions, missing observations or real pupil figures.

Growth comparison knowledge continued

White standard edition

Invented model only

These figures are invented for a model. They are not real tray records, expected growth or a target. The imaginary comparison intends only light to differ; it describes other conditions as alike.

Invented measure	A brighter position	B dimmer position
Week 2 height	3 cm	3 cm
Week 2 whole leaves	1	1
Week 5 height	10 cm	14 cm
Week 5 whole leaves	4	3
Week 5 condition	Green and firm	Pale and leaning

In the model, A gains 7 cm and B gains 11 cm from Week 2. B is 4 cm taller at Week 5, but has fewer whole leaves and pale leaning growth. Taller alone does not mean healthier.

Light may contribute, but one tray per condition does not prove a cause. Do not copy any of these numbers into the real record.
