

Shared evidence | Disease case board

Disease detectives: follow the cause

Name _____ Date _____

Teaching summaries for classification. Do not use these cards to diagnose yourself or anyone else.

A | Tuberculosis

Caused by bacteria. The infectious cause can pass through the air. Coughing can occur.

C | Malaria

Caused by protists. Certain mosquitoes can carry the pathogen between people.

E | Coronary heart disease

A non-communicable disease. Inherited, environmental and behavioural factors can affect risk.

B | Cholera

Caused by bacteria. People can become infected through contaminated water or food.

D | Asthma

A non-communicable airway condition. Coughing can occur; asthma is not passed between people.

F | Influenza

Caused by influenza viruses. Infection can spread between people; antibiotics do not treat the virus.

W1. Sort A-F. W2. Explain a route interruption. W3. Repair the cough headline.

Supported route | Follow the evidence

Word bank: communicable; non-communicable; pathogen; bacteria; protist; vector; not certain.

S1. Put A-F into the two disease categories. Give one clue for C and one for D.

S2. Complete the malaria route using person, mosquito and protist. What is the vector?

S3. Choose safer water/food or a mosquito barrier for cholera. Explain which route it interrupts.

S4. Why does a shared cough not prove the same cause? Use A and D.

Standard route | Write the case report

Use the shared cards. Short, precise scientific sentences are enough.

M1. Classify A-F and justify two different communicable transmission routes.

M2. Explain how a malaria barrier could reduce transmission. Distinguish pathogen and vector.

M3. Explain why coughing alone cannot show whether a disease is communicable.

M4. Improve: "A risk factor means someone will develop heart disease." Include more than one type of influence.

Stretch route | Challenge the conclusion

Optional transfer. New fictional cases: G is caused by a fungus whose spores pass through air. H is an inherited blood condition with no infectious cause.

T1. Classify G and H. Explain why “inherited” is not the same as communicable.

T2. A town reports more coughing after dusty construction work. Does this prove an infectious outbreak? Give another plausible cause and one type of additional evidence.

T3. A poster says antibiotics cure every communicable disease. Evaluate it using two pathogen types from the cards.

T4. Explain why a prevention method can reduce risk without guaranteeing that no infection occurs.

Exit and reflection | Cause, route, risk

Use accurate scientific words or annotated arrows.

E1. What makes a disease communicable?

E2. Name malaria's pathogen type and its vector.

E3. Why is cough alone insufficient to classify a disease?

L1. What did your audience ask? Which explanation did you improve or defend?

My next useful step

- A. Identify the infectious cause.
- B. Trace direct or indirect transmission.
- C. Use risk language carefully.
