Knowledge organiser (SUMMIT) — Material implementation and critical development

Pathway: SUMMIT · Week 3 Part 2 · Big question: How do we translate our Week 1-2 studio brief and joint prototypes into a multi-level structural relief build?

Core studio focus

Family: Studio suite

Big question: How do we translate our Week 1-2 studio brief and joint prototypes into a multi-level structural relief build?

• Construct the primary and secondary structural planes of your site-specific relief panel following your Week 1 elevation.

• Integrate laminated load-bearing spans, negative-space voids, and embossed metallic gussets with precision joinery.

• Apply a base monochromatic ground and record a mid-build critical log note on structural tension and shadow depth.

Essential vocabulary

• implementation: Turning a drawn design brief and prototype into the full physical artwork.

• plane: A distinct flat or textured depth level (background plane, midground plane, foreground plane).

• cantilever: A rigid structural beam that projects horizontally beyond its vertical support.

• monolithic: Reading as one unified, heavy, solid structure rather than separate scraps.

• shadow line: The crisp dark line cast underneath a projecting relief flange.

Three-step studio method

Step 1: Dry-fit and bond Plane 1 textures: Following my Week 1 elevation, I position corrugated fluting in the recessed bays while keeping the triangular sky voids clean.

Step 2: Engineer and bond Plane 2 laminated spans: I cut and laminate my primary arch and cantilever beams using a safety ruler, then bond them cleanly over Plane 1.

Step 3: Add plane 3 embossed gussets and prime: I lock the beam intersections with embossed foil gusset plates, apply dark iron primer into the recessed joints, and write my mid-build log note.
