

One symptom. Two explanations.

Learning intention

Distinguish communicable and non-communicable disease using cause and transmission evidence.

Mission: solve disease evidence cards without guessing a diagnosis.

You may point, discuss quietly or write.

Cause, symptom or risk?

R1. Are all microorganisms harmful?

R2. Is a symptom the same as its cause?

R3. Does a higher chance mean certainty?

I follow the causal evidence

Classify using the cause, not the symptom

**Communicable
Transmissible pathogen**

**Non-communicable
Not transmitted**

**Tuberculosis: bacterium
Can involve coughing**

**Asthma: airway condition
Cough can occur**

The same symptom can have different causes.

My first question: is there a transmissible infectious cause? I do not classify from how unwell someone looks.

Transmission can be indirect

Malaria: a vector connects hosts

A route through a vector is still communicable.
A bite does not automatically mean infection.

A vector can carry a pathogen between hosts. Follow the arrows and name the pathogen.

A careful explanation of risk

Risk is not a single switch

Risk is not certainty. Illness is not a blame label.

Several factors can affect disease risk. “More likely” is different from “will happen”.

Case-board challenge

W1. Sort A–F into communicable or non-communicable. Use the cause column as evidence.

Case	Cause/category	Transmission clue
A: tuberculosis	Bacteria	Air
B: cholera	Bacteria	Contaminated water/food
C: malaria	Protist	Mosquito vector
D: asthma	Non-communicable	Not transmitted
E: coronary heart disease	Non-communicable	Not transmitted
F: influenza	Virus	Between people

Supplied teaching summaries; not diagnostic guidance.

Interrupt one route

Malaria: a vector connects hosts

A route through a vector is still communicable.
A bite does not automatically mean infection.

W2. Choose a route: cholera or malaria. Match it to safer water/food or a mosquito barrier. Explain the link rather than naming a cure.

Repair the false headline

W3. “Both people cough, so both have the same communicable disease.”

Use A and D to improve the headline.

Which statement is scientifically sound?

Choose, then justify with a card.

- A** Malaria is non-communicable because a vector is involved.
- B** A communicable disease has an infectious cause that can spread.
- C** A shared symptom proves the same cause.
- D** One risk factor guarantees disease.

Build an evidence-based explanation

Choose your agreed response page.

Use the supplied cards, not personal health examples.

Independent case report

Classify → cite a clue → trace a route → check a claim.

Aim for accurate reasoning, not a long answer.

Let evidence change a decision

L1. Offer one classification and your strongest clue.

Your audience asks: “Does that clue identify the cause?”

A defensible case report

Name the category and causal evidence.

Keep probability separate from certainty.

Three scientific distinctions

E1. Define communicable.

E2. Name malaria's pathogen type and vector.

E3. Why can cough alone not classify a disease?

Your next useful step

Circle one: cause • route • risk.

Keep one explanation you improved.
