I can order copy, separate and split for mitosis.

I can mark one gene as part of DNA.

I can use a simple cross as probability, not a promise.

I am learning to use cell and inheritance models to show what I know and choose one next step.

DNA is copied before mitosis. The copies separate into matching sets in two nuclei. The cell then splits.

A chromosome contains DNA. A gene is one section of DNA. An allele is a version of a gene.

A simple cross shows possible allele pairs and their chances. It does not promise an exact family count.

Use a model detail as evidence. State one limit. Keep your first answer and one precise next step.
