Pupil studio resources & worksheet — Material implementation and critical development

Pathway: SUMMIT · Week 3 Part 2 · Big question: How do we translate our Week 1-2 studio brief and joint prototypes into a multi-level structural relief build?

Arrival check

Open your Week 1 elevation brief and your Week 2 corner-joint prototype. Which plane of your main relief board must be engineered and bonded first?

[ ] Plane 1 (the recessed background textures and voids) so Plane 2 and Plane 3 beams can bridge cleanly over the top

[ ] Checking alignment dry against your Week 1 elevation before gluing prevents crooked spans

[ ] Sealing the structural card layers with a dark base primer makes the whole piece look monolithic

Starter visual cues

Plane 1 (Recessed ground & Voids): Bond textured fluting/mesh zones while leaving crisp open negative-space voids.

Plane 2 (Primary structural Frame): Laminate double-thickness greyboard girders to span across Plane 1.

Plane 3 (Foreground gussets & Foil plates): Add embossed rivet plates and projecting flanges at key load joints.

Mid-Build critical Check: Prime recessed seams and log one adjustment for directional shadow.

Vote: Why do we build laminated double-thickness beams for Plane 2 and Plane 3 rather than using single thin paper strips?

Studio practice planner

Execute your three-plane structural build.

Shapes/Focus: Plane 1: Recessed fluting & voids, Plane 2: Laminated primary span, Plane 3: Embossed foil gussets, Detail: Undercut shadow spacers

Tools/Methods: Joinery: Safety-ruler precision, Joinery: Thin spreader PVA bond, Surface: Dark iron base primer, Audit: Side-light shadow check

Exit ticket

How do you create a deep 'undercut' shadow line beneath a foreground card beam in relief construction?

[ ] Glue a slightly narrower hidden spacer strip underneath the middle of the beam so its outer edges overhang and trap dark shadow

[ ] Draw a pale yellow line on top

[ ] Squash the beam completely flat into wet glue
